

Andrew Prodromou ST5 EoE

Case 20 Palpable mass, left breast. Needle core biopsy

- Section of breast shows a fibroepithelial lesion together with an increase of stromal cellularity and mild cellular atypia.
- Subtle stromal cuffing of the epithelial cells is seen.
- There is no mitoses or stromal overgrowth seen

Diagnosis: Breast: cellular fibroepithelial lesion

Comment

Due to the limitations of a breast core it is difficult to distinguish between fibroadenoma vs a phylloides tumour & therefore uncertain to predict the behaviour of this fibroepithelial lesion.

Best to regard as a B3
