

## Case 18

Section show normal salivary gland tissue at one end of the tissue. There are areas showing atrophy of the acini with prominent salivary ducts surrounded by dense lymphocytic infiltrate. Lympho-epithelial lesions are identified. There are no granulomas identified. There is no evidence of epithelial malignancy.

### Diagnosis

Lymphoepithelial sialadenitis with ~~possible~~ <sup>possible</sup> progression to low grade lymphoma.

### Additional work up

- I put a similar table as described in case 12
- I also said I will perform clonality testing.
